7. Traditional orchards

Climate change sensitivity: **Low**
Introduction

The species composition and structure of traditional orchards are determined by management, which provides a mechanism to respond to the impacts of climate change. Orchards are sensitive to the impacts of drought, warmer winters, and the potential for more storms, but these impacts can be mitigated by changes in management and appropriate replacement and replanting. Although it may be possible in the long term to plant new varieties in response to climate change, fruit trees live anywhere from 70 – 200 plus years, so there is a risk of existing trees either dying or being replaced because they are not commercially viable any more, before any new planting matures enough to create replacement habitat. This would also have a detrimental impact on the genetic conservation of rare varieties. Indirect impacts, such as changes to the economics of orchards and a shift from traditional crops to new ones that require more intensive management, may pose a greater threat.

Habitat Description

Traditional orchards are defined as groups of fruit and nut trees planted on vigorous rootstocks at low densities in permanent grassland orchards and managed in a low intensity way. This contrasts with orchards managed intensively for fruit production which often use short-lived, high-density, dwarf or bush fruit trees, and are characterised by the input of chemicals such as pesticides and inorganic fertilisers, and frequent mowing of the orchard floor rather than grazing or cutting for hay. Habitat structure rather than vegetation type, topography or soils, is the defining feature of orchard habitats.

Traditional orchards are structurally and ecologically similar to wood-pasture and parkland, with open-grown trees set in herbaceous vegetation, but are generally distinguished from this habitat by the species of tree (being primarily of the family Rosaceae), the generally denser arrangement of the trees, and the small size of individual habitat patches.

Management of the trees is the other main feature distinguishing traditional orchards from wood-pasture and parkland. Trees in traditional orchards are, or were, grown for fruit and nut production, usually achieved through practices such as grafting and pruning; whereas the main product from trees in wood-pastures and parkland has been timber, mostly derived from pollarding or selective felling.

Grazing or cutting the understorey is integral to orchard management, as it is in wood-pasture and parkland. The presence of scrub, mostly in the form of hedgerows on the site boundaries, or sometimes, especially in unmanaged orchards, among the orchard trees, is analogous to the frequent occurrence of scrub in wood-pasture and parkland, and plays a similar ecological role. Ponds and other wetland features are often present, being used now or in the past for watering livestock.

Traditional orchards are found throughout the lowlands of England, although there are concentrations in Kent, Cambridgeshire, Somerset, Herefordshire, Worcestershire and Gloucestershire. The estimated area in England is 17,000ha.
## Potential climate change impacts

<table>
<thead>
<tr>
<th>Cause</th>
<th>Consequence</th>
<th>Potential impacts</th>
</tr>
</thead>
<tbody>
<tr>
<td>Drier summers</td>
<td>Drought</td>
<td>- A reduction in available moisture during the growing season can lead to root stress, possible defoliation, premature fruit drop, or low fruit size.</td>
</tr>
</tbody>
</table>
| **Warmer summers**     | Warmer temperatures and a longer growing season. | - Temperatures constantly in the high 20°Cs, when associated with drier conditions, can cause heat stress (see above). Continued warm autumn weather with adequate moisture may compensate for some of these effects.  
- Hotter, drier summers may see an increase in the occurrence of powdery mildew (*Podosphaera leucotrica*), especially in the south west.  
- Fire blight (*Erwinia amylovora* bacterium) favours warm, humid conditions and so could become more widespread in wet springs.  
- Warmer summers may result in increased in pest damage, where pest populations increase or new pests arrive from overseas.  
- Warmer conditions could lead to traditional orchard fruit species being replaced by fruit currently grown in more southern locations, such as peaches, that require more intensive management.  
- Warmer, drier summers may change the composition of species-rich swards, as with other grassland. |
| **Warmer winters**     | Fewer frost events                | - Fewer frosts will result in greater over-wintering survival of insect pests, leading to higher populations and greater pressure on trees.  
- Apple trees need several weeks of relatively cold weather to complete dormancy. Warmer average winter temperatures will give inadequate periods of vernalisation\(^{18}\). This will affect different apple varieties in different ways: some may flower too early, risking damage from late frosts; some may flower at a different time from their pollinator; and varieties requiring a longer dormancy may develop ‘blind buds’ that fail to develop in spring.  
- Sporadic flowering over a prolonged period may lead to pollination problems.  
- Poor leaf quality at flowering time will lead to poor fruit set. |
| Wetter Winters         |                                  | - Wet and warm weather from autumn to spring could increase the risk of scab *Venturia inequalis*.  
- Wet soil conditions will increase the risk of wind throw in windy weather.  
- Prolonged wet soil conditions with poor drainage will increase the risk of tree death from water-logging, or crown rot caused by Phytophthora spp. |
| Increased frequency of extreme events | Heat Waves  
Extremes of soil temperature and moisture  
Increased frequency of storms | - Some varieties of apple can suffer from sun scorch in hot weather.  
- High winds, coupled with water-logged soil, may increase the frequency of wind throw, leading to the loss of mature and veteran trees.  
- Severe storms can increase the spread of pests and diseases such as fire blight. |
| In combination          |                                  | - General disruption of the natural yearly fruit tree cycle may increase biennial cropping. Extreme weather such as warm springs followed by late frosts, unseasonal wet weather and hail storms can have negative impacts on pollination and fruit set.  
- Warmth-loving invertebrates associated with dead wood, possibly including the rare noble chafer beetle *Gnorimus nobilis* may spread northwards, but could be lost in the south.  
- Bird species that nest in orchards, such as redstart and woodpeckers may be lost, while other species, including Wryneck and Hoopoe, may become established.  
- Current winter species, including redwing and fieldfare, may no longer visit. Other species may start wintering here with warmer winters, eg blackcap have started wintering in south east England and may spread (they feed on mistletoe berries and may be responsible for increasing the spread of mistletoe in the south east). |

\(^{18}\) The subjection of seeds or seedlings to low temperature in order to hasten plant development and flowering
Adaptation responses

The influence of historic and current management on the structure, function and condition of traditional orchards provides a high degree of flexibility in designing appropriate adaptation strategies and managing change. Continuing, or reintroducing, low input active management of traditional orchards is a key adaptive response. Increasing the species and structural diversity of orchards at a site and landscape scale will also reduce vulnerability. Selection of the appropriate species and cultivars for the site will also play a role in future proofing orchards against climate change.

Some of the potential adaptation options for this habitat are outlined below.

- Ensure continued extensive management of orchards, with little or no agrochemical input, and using grazing rather than machinery to manage the understory.
- Adjust grazing levels according to environmental conditions to avoid under and over-grazing and compaction.
- Minimise soil erosion by grassing-down alleyways. Alleyways are a feature of bush orchards rather than traditional orchards, which have permanent grass swards.
- Increase the age structure and variety of species within orchards through management and replanting.
- Consider selecting more drought-tolerant species, or provenance from the southern part of a species’ range when replanting. This may not always be possible, for example if no cider varieties are able to be grown, then the cider industry would have to import fruit and therefore have no reason to conserve orchards.
- Select varieties with lower dormancy requirements. Many late flowering, late maturing varieties, especially cider apples, require greater cold vernalisation than early flowering varieties. This may conflict with the genetic conservation of rare, localised varieties.
- Ensure that all planting material complies with the EU plant passport scheme, which includes a requirement for freedom from fireblight.
- Establish windbreaks for shelter prior to planting trees and use strong tree support systems on exposed sites.
- Manage mature trees to reduce the threat of wind rock and wind throw. For example, encourage sustainable mistletoe harvesting from trees exposed to high winds.
- Plan for changes in the availability and demand for water by, for example, increasing on-farm water storage capacity or installing a trickle irrigation system.
- Ensure the continued presence of decaying wood within live trees, by prolonging the life of old trees and retaining dead wood.
- Develop contingency plans for outbreaks of new pests and diseases and other extreme events. Ensure regular monitoring of pests and diseases and adhere to best practice in integrated pest management.
- Consider the use of natural products and biocontrol agents for mildew control, and select resistant varieties in new planting.
Relevant Environmental Stewardship options

*Maintenance of high value traditional orchards (HC18)*

This option aims to maintain existing traditional orchards that are generally in good condition and that are being managed extensively for wildlife and historic landscape benefits. Some planting of traditional varieties of orchard trees species may be required if there are gaps in the orchard. Ongoing management will require suitable livestock grazing and the protection and maintenance of the trees. Capital payments may be made for restorative pruning of old trees.

*Maintenance of traditional orchards in production (HC19)*

This is aimed at orchards currently managed on a commercial basis where fruit production and tree health are important considerations. Appropriate fertilisers, pesticides and management techniques are allowed. If more restorative pruning or new planting is required the restoration option should be considered.

*Restoration of traditional orchards (HC20)*

This option applies to existing traditional orchards, managed extensively for wildlife and historic landscape benefits, that are under-stocked or in need of restoration. The option aims to restore degraded orchards by re-planting traditional varieties of orchard trees to restore tree numbers to an appropriate level.

*Creation of traditional orchards (HC21)*

This option is highly targeted to re-creating orchards on sites that are known to have previously been orchard. The option may also be used in appropriate areas to help support specific threatened species such as the rare noble chafer beetle. Planting of traditional varieties of orchard tree species will usually be required in the first two years of the option.
Further information and advice

Natural England has produced a number of publications about orchards, including the following Technical Information Notes. These can be found [here](#).

Farming Futures Climate Change Series Fact Sheet 16 - [Focus on apple and pear orchards](#).
